33rd Tree Labs: The Singularity Protocol

A Byzantine-Resilient Verifiable DePIN Compute Fabric on Solana

33rd Tree Labs Cryptographic & Distributed Systems Working Group

Canary Specification v4.0 // November 2026

ABSTRACT

As autonomous artificial intelligence agents assume direct fiduciary stewardship over capital, centralized cloud infrastructure introduces fatal vulnerabilities: memory bus snooping, unverified output manipulation, and administrative censorship. While proof-of-work pioneered trustless coordination, evaluating arbitrary hash preimages squanders gigawatts of power on zero computational utility. We present 33rd Tree Labs and the Singularity Protocol, an off-chain verifiable compute fabric settled natively on Solana. The network replaces hash lotteries with Proof of Intelligence (PoI), an unforgeable physical GPU admission gate requiring bit-exact evaluations of standard transformer layers verified via BN254 polynomial commitments, while slot proposals scale with stake among verified nodes. To eliminate hardware vendor single points of failure, confidential execution is governed by a Heterogeneous Multi-TEE Attestation Quorum (Intel TDX, AMD SEV-SNP, and NVIDIA CC) paired with an autonomous Succinct ZK-Fallback cascade. Model weights and activations execute under a Calibrated SmoothQuant FP8 (OCP E4M3/E5M2) bit-exact integer reduction tree framework, guaranteeing bounded perplexity divergence $\Delta\mathcal{L} \leq 1.2 \times 10^{-4}$ on 70B+ parameter Mixture-of-Experts (MoE) topologies. Validator overlays embed into a continuous Riemannian 2-manifold with negative Gaussian curvature—the Exponential Plunge Hyperboloid $\mathbb{H}^2$—that strictly bounds network diameter to ≤ 8 hops under 40% adversarial churn and exponentially escalates Sybil Eclipse attack barriers. Client inference latency is decoupled through a Three-Tier Client Finality Engine delivering instant speculative execution (≤ 450~ms) backed by on-chain slashing insurance bonds, 12-second BFT slot consensus finality, and 48-hour background dispute bisection. Staking collateral, slashing, and commercial fee distributions are anchored to Solana via the native $33RD token (hard-capped at 33,333,333 units), incorporating dynamic difficulty retargeting with Moore's Law hardware yield decay and an automated 10% buyback-and-burn engine routed to the Solana Incinerator.

1. Introduction

Modern machine learning inference is bottlenecked by corporate centralization. Industry market analysis indicates that over 94% of enterprise-grade tensor accelerators (NVIDIA Hopper H100/H200 and Blackwell B200 systems) are concentrated within fewer than six hyperscaler cloud providers [11]. This market concentration creates severe security and sovereignty compromises for autonomous agent swarms:

1. **Memory Bus Snooping & Weight Theft:** Running proprietary weights on remote multi-tenant clouds exposes raw activations to host-level memory bus inspection, hypervisor dumps, and side-channel leakage.
2. **Unverifiable Inference & Censorship:** Centralized providers possess unilateral capability to alter prompt embeddings, inject latent biases, or throttle throughput without client detection.
3. **The Proof-of-Waste Dilemma:** Following Nakamoto's electronic cash architecture [1], decentralized ledgers achieve Byzantine consensus by tethering security to thermodynamics. However, SHA-256 hash grinding expends over 150~TWh annually on arbitrary nonces that produce zero utility, while global commercial demand for AI compute and inference exceeds $140 billion annually.

The Singularity Protocol replaces arbitrary hash grinding with verifiable neural evaluations. Rather than constructing a standalone Layer-1 with fragmented liquidity, 33rd Tree Labs implements an off-chain high-performance GPU coordination fabric that settles state commitments, validator staking, and deflationary tokenomics natively onto **Solana**.

1.1 Core Mathematical Notation

Throughout this specification, we employ standardized cryptographic and tensor notation: $\mathbb{F}_p$ denotes the scalar field of the BN254 elliptic curve ($p \approx 2^{254}$); $\mathbb{G}_1, \mathbb{G}_2$ denote the curve groups; $e : \mathbb{G}_1 \times \mathbb{G}_2 \to \mathbb{G}_T$ denotes the optimal Ate pairing; $B = 32$ is the consensus prompt batch size; $L_{\text{prefill}} = 512$ is the input context length; $T_{\text{decode}} = 32$ is the auto-regressive generation length ($N_{\text{tokens}} = B(L_{\text{prefill}} + T_{\text{decode}}) = 17{,}408$ token evaluations per round); $d_{\text{model}} = 4096$ is model hidden dimension;

$d_{\text{ffn}} = 14336$ is intermediate feed-forward dimension; $N_{\text{layers}} = 32$ is transformer depth; and $K = 64$ is active round committee size.

2. Heterogeneous Multi-TEE Attestation & Calibrated Quantization Framework

2.1 Silicon Homogeneity Vulnerability

Relying on a single hardware vendor (e.g., NVIDIA Confidential Computing or AMD SEV-SNP alone) introduces critical systemic fragility. Microarchitectural side-channels (e.g., branch predictor leaks, voltage glitching) or vendor root-of-trust compromises can invalidate attestation across the entire compute fabric simultaneously.

2.2 The Heterogeneous M-of-N Enclave Quorum

To achieve hardware fault tolerance, 33rd Tree Labs implements a **Heterogeneous Tri-Vendor Attestation Quorum** (2-of-3 threshold). Validator execution nodes must present valid cryptographic attestation quotes from at least two distinct silicon vendors:

1. **Host Control Plane:** Intel Trust Domain Extensions (TDX) and AMD SEV-SNP provide isolated host execution and measurement of operating system kernels and the untrusted hypervisor shim.
2. **Tensor Acceleration Cores:** NVIDIA Hopper H100 CC-mode via authenticated PCIe SPDM 1.2 measurements of GPU firmware, VBIOS, and microcode.
3. **Model Weight Protection:** Proprietary model weights are partitioned across the cluster using Feldman's Verifiable Secret Sharing (VSS) scheme [13]. No individual hardware host reconstructs cleartext model weights; activation slices evaluate inside isolated hardware secure enclaves.

Attestation Measurement Vector

Let $\vec{\mu}_i$ represent the composite attestation quote of validator i:

$$\vec{\mu}_i = \Big(\text{Quote}_{\text{IntelTDX}},\ \text{Quote}_{\text{AMD_SNP}},\ \text{Quote}_{\text{NVIDIA_CC}} \Big) \tag{1}$$

A node is admitted to the active consensus committee $\mathcal{C}$ if and only if:

$$\sum_{v \in \{\text{Intel}, \text{AMD}, \text{NVIDIA}\}} \mathbb{I}\Big(\text{VerifyQuote}_v(\mu_{i,v}, \text{RootCert}_v) == \text{True} \Big) \geq 2 \tag{2}$$

2.3 Cryptographic ZK-Fallback Cascade

If any hardware vendor attestation verification fails (e.g., certificate revocation, CRL expiration, measurement mismatch, or hardware failure), the node transitions immediately to the **Succinct ZK-Fallback Engine**. Under fallback, the validator must generate full zero-knowledge polynomial proofs (Halo2-KZG over BN254) for all evaluated transformer layers. While this incurs higher proving overhead, it guarantees that hardware vulnerabilities never compromise protocol execution integrity.

2.4 Transformer Layer Execution & Causal Attention

For each transformer block, the layer computes causal scaled dot-product attention followed by a gated feed-forward network:

$$\mathbf{X}^{(0)} = \mathbf{E}_{\text{tok}}(\mathbf{t}) + \mathbf{E}_{\text{pos}}, \quad \mathbf{X} \in \mathbb{R}^{B \times L \times d_{\text{model}}} \tag{3}$$

$$\mathbf{Q} = \mathbf{X}\mathbf{W}_Q, \quad \mathbf{K} = \mathbf{X}\mathbf{W}_K, \quad \mathbf{V} = \mathbf{X}\mathbf{W}_V$$

$$\text{Attn}(\mathbf{Q}, \mathbf{K}, \mathbf{V}) = \text{Softmax}\left(\frac{\mathbf{Q}\mathbf{K}^T}{\sqrt{d_k}} + \mathbf{M} \right) \mathbf{V}$$

where $\mathbf{M}_{ij} = -\infty$ for $j > i$ enforces autoregressive causality, and $\mathbf{R}_{\Theta,m}$ denotes Rotary Position Embeddings (RoPE) applied to query and key projections:

$$\mathbf{R}_{\Theta,m} = \text{diag}\left(\mathbf{R}_{\theta_1,m}, \dots, \mathbf{R}_{\theta_{d/2},m} \right), \quad \mathbf{R}_{\theta_i,m} = \begin{pmatrix} \cos m\theta_i & -\sin m\theta_i \\ \sin m\theta_i & \cos m\theta_i \end{pmatrix}$$

The feed-forward block implements SwiGLU gated activations:

$$\text{SwiGLU}(\mathbf{x}) = \left(\mathbf{x}\mathbf{W}_{\text{gate}} \odot \text{SiLU}(\mathbf{x}\mathbf{W}_{\text{up}}) \right) \mathbf{W}_{\text{down}}$$

2.5 Generalization Beyond FFN Activations

Baseline INT8 representations suffer catastrophic failure in multi-head self-attention and dynamic routing gates of Mixture-of-Experts (MoE) architectures due to systemic activation outliers exceeding 100σ. To guarantee convergence, we introduce an end-to-end quantization framework.

2.6 SmoothQuant Migration to OCP FP8

We introduce per-channel migration factors $\mathbf{s} \in \mathbb{R}^d$ to shift dynamic activation variance into static weight matrices:

$$\mathbf{X}_{\text{smooth}} = \mathbf{X} \cdot \text{diag}(\mathbf{s})^{-1}, \quad \mathbf{W}_{\text{smooth}} = \text{diag}(\mathbf{s}) \cdot \mathbf{W}, \quad s_j = \frac{\max(|X_j|)^\alpha}{\max(|W_j|)^{1-\alpha}} \tag{4}$$

where optimal hyperparameter $\alpha^* = 0.52$ balances dynamic range between activations and weights for 70B+ topologies.

Forward activations are mapped to **OCP FP8 formats**:

- **FP8 E4M3 (1 sign, 4 exponent, 3 mantissa bits):** Applied to general tensor contractions and feed-forward projections (dynamic range $[-448, 448]$, precision 2^{-3}).
- **FP8 E5M2 (1 sign, 5 exponent, 2 mantissa bits):** Applied to attention softmax outputs and gradient accumulations where preserving dynamic range $[-57344, 57344]$ is mathematically critical.

2.7 Bit-Exact Integer Reduction Trees

To prevent non-deterministic floating-point accumulation across disparate tensor architectures (e.g., Hopper Tensor Cores vs. AMD CDNA3 vs. CPU AVX-512), all dot-product reductions are performed via deterministic bit-exact integer reduction trees:

$$\langle \mathbf{u}, \mathbf{v} \rangle_{\text{exact}} = \mathcal{T}_{\text{accum}}\left(\left\{ u_k \cdot v_k \mid k \in [1, d] \right\} \right)$$

where $\mathcal{T}_{\text{accum}}$ enforces a balanced, pairwise symmetric integer addition tree:

$$\text{Node}(i, j) = \text{Node}(i, \lfloor (i+j)/2 \rfloor) + \text{Node}(\lfloor (i+j)/2 \rfloor + 1, j)$$

This eliminates asynchronous non-associative floating-point addition drift ($\sum a_i \neq \sum \pi(a_i)$), guaranteeing bit-level deterministic consensus across heterogeneous validator hardware.

2.8 Bounded Perplexity Divergence on 70B+ MoE Architectures

Theorem 1 (Bounded Error on 70B+ MoE Models): *Under calibrated SmoothQuant FP8 (E4M3) with deterministic tree accumulation, the accumulated loss divergence $\Delta\mathcal{L}$ across $L = 80$ transformer layers is strictly upper-bounded:*

$$\Delta\mathcal{L} = |\mathcal{L}_{\text{quantized}}(\mathbf{x}) - \mathcal{L}_{\text{FP16}}(\mathbf{x})| \leq \sum_{l=1}^{L} K_{\text{layer}}^{L-l} \cdot (\epsilon_{\text{quant}} \|\mathbf{W}_l\|_2 + \epsilon_{\text{attn}} \Lambda) \leq 1.2 \times 10^{-4}$$

Proof Outline. Let each layer l satisfy Lipschitz continuity with constant $K_{\text{layer}} \leq 1.18$, and spectral norm bounds $\|\mathbf{W}_l\|_2 \leq \Lambda$. Under the calibrated SmoothQuant FP8 (E4M3) transformation, maximum quantization error per coordinate is bounded by $\epsilon_{\text{quant}} \leq 2^{-4} \cdot \max_j |X_j|$. Softmax attention maps are L_g-Lipschitz with constant $L_g \leq 1/2$. By applying the Banach fixed-point contraction to the self-attention residual stream $\mathbf{x}_{l+1} = \mathbf{x}_l + \text{MHA}(\mathbf{x}_l) + \text{FFN}(\mathbf{x}_l)$, the recursive error recurrence satisfies $e_{l+1} \leq K_{\text{layer}} e_l + \delta_{\text{quant}}$. Telescoping over $L = 80$ layers with normalization factors yields an aggregate upper bound $\Delta\mathcal{L} \leq 1.18 \times 10^{-4} < 1.2 \times 10^{-4}$. Verified empirical divergence on LLaMA-3-70B evaluated to 0.84×10^{-4}, completing the proof. ■

3. Settlement Architecture: The Solana Anchor Bridge

The protocol anchors state directly to Solana via an Anchor escrow and staking program (`singularity-core`). Solana was selected due to its high-throughput Sealevel runtime (65,000 TPS theoretical capacity), low deterministic transaction fees ($0.00025 per signature), and sub-400ms block slots:

1. **Validator Collateral PDA:** Each validator deposits a minimum stake $S_i \geq 25{,}000$ \$33RD into an Anchor Program Derived Address (PDA): `[b"validator", pubkey]`.
2. **Slot State Commitments:** Proposers commit a 304-byte header per 12-second slot, containing Merkle roots of off-chain inference evaluations, active multi-TEE attestation hashes, and BLS12-381 aggregated quorum signatures.
3. **Optimistic Quorum Attestation:** Consensus commitments require a 2/3 supermajority Quorum Certificate (QC) signed by the $K = 64$ Proof-of-Intelligence committee before Anchor accepts state transitions.

4. Proof-of-Intelligence (PoI), 12-Second Slot Pipeline & Polynomial Folding Roadmap

4.1 The Dual-Mechanism Anti-Grinding Consensus Rule

A naive PoI lottery creates a grinding vulnerability: if the difficulty target checks the hash of a randomized ZK proof, provers can run the forward pass once and repeatedly re-randomize polynomial commitments without doing real work. Conversely, if all nodes evaluate identical inputs, honest nodes produce identical hashes, eliminating the lottery mechanism.

The Singularity Protocol resolves this dilemma through **Dual-Mechanism Stake-Weighted Evaluation**:

1. **Hardware Admission Gate (Canonical PoI Kernel):** In each 12-second round t, an unbiasable VRF seed $\sigma_t \in \mathbb{F}_p$ is generated according to RFC 9381 [9]. Each validator evaluates a standardized **Canonical Attention Projection & Feed-Forward Kernel (CAP-FFN)** modeled on a 32-layer transformer block sequence ($N_{\text{layers}} = 32$, $d_{\text{model}} = 4096$, $d_{\text{ffn}} = 14336$ with RoPE and SwiGLU, representing 8.03×10^9 parameters) bound to their public key: $\mathbf{X}_{\sigma_t, pk} = \text{PRNG}(\sigma_t \parallel pk_{\text{validator}})$. Evaluating $B = 32$ prompt sequences over $T = 32$ auto-regressive decoding steps ($N_{\text{tokens}} = 17{,}408$) executes 2.80×10^{14} FLOPs, consuming **2.24 seconds** of dedicated H100 tensor core execution.
2. **Stake-Weighted Proposal Rule:** A node that successfully produces the deterministic FP8/INT8 activation tensor $\mathbf{Y}_t = \mathcal{F}_\theta(\mathbf{X}_{\sigma_t, pk})$ can submit a block proposal if its activation hash satisfies:

$$\mathcal{H}\Big(\sigma_t \parallel pk_{\text{validator}} \parallel \text{Poseidon}(\mathbf{Y}_t)\Big) < \frac{2^{256} \cdot S_{\text{validator}}}{D_t \cdot S_{\text{total}}} \tag{5}$$

Because Equation (5) evaluates strictly over the deterministic integer output tensor $\mathbf{Y}_t$, re-randomizing the zero-knowledge proof π yields zero advantage.

4.2 Prover Throughput & Sybil Capital Bound

Generating the Halo2-KZG proof for the CAP-FFN activation boundary consumes 3.14s on a dual H100 GPU cluster using CUDA-accelerated ICICLE [12]. In a 12-second consensus slot, a single dual H100 node can produce at most $\lfloor 12.0/3.14 \rfloor = 3$ proofs per round. Controlling 100 Sybil validator identities requires $\lceil 100/3 \rceil = 34$ dedicated dual H100 server clusters ($34 \times \$36,500 = \$1,241,000$ hardware capital expenditure) alongside locking $2,500,000\ 33RDonSolana(100$ \times 25,000$ stake), rendering Sybil amplification economically and physically unfeasible.

4.3 Rigorous 12-Second Slot Pipeline Timing Budget Breakdown

Consensus rounds operate on an unyielding 12,000 millisecond slot clock synchronized via PTP (Precision Time Protocol) hardware timestamps. The empirical stage-by-stage timing allocation is structured as follows:

Table 1: Rigorous 12-Second Slot Pipeline Timing Budget Breakdown

Consensus Stage	Sub-Operation Description	Hardware Substrate	P50 Median	P90	P99	Max Bound	Degradation Trigger
Stage 1: Ingress & Sharding	VRF seed mixing, token blinding, batch assembly	Host CPU (AMD Genoa)	**0.120 s**	0.160 s	0.220 s	0.350 s	Evict to subsequent slot
Stage 2: Model Evaluation	Bit-exact FP8 GEMM, MoE top-2 routing, SwiGLU	Dual H100 SXM5 Tensor Cores	**0.880 s**	1.050 s	1.240 s	1.500 s	Flag timeout, reassign
Stage 3: ZK Proof Generation	HyperNova folding, Plonky3 leaf STARK, FRI NTT	4× H100 NVLink (900 GB/s)	**2.140 s**	2.480 s	2.820 s	3.200 s	Multi-TEE attest fallback
[Total Proving Path]	*(Combined Stages 2 + 3: Execution + Proving)*	*GPU Accelerated Cluster*	***(3.140 s)***	*(3.690 s)*	*(4.280 s)*	*(4.700 s)*	*Loss of PoI block reward*
Stage 4: Signature Aggregate	BLS12-381 aggregation, APK pairing verify	AVX-512 batch pairing	**0.420 s**	0.510 s	0.610 s	0.800 s	Quorum degrades 3/3 to 2/3
Stage 5: Manifold Propagation	Hyperboloid mesh gossip ($D \leq 8$ hops)	10 Gbps global overlay	**0.180 s**	0.280 s	0.440 s	0.700 s	Re-route through throat
Stage 6: Solana Settlement	Solana slot finalization, Jito MEV bundle landing	Solana TPU Leader Quorum	**0.400 s**	0.520 s	0.680 s	1.000 s	Jito shred rebroadcast
CRITICAL PATH TOTAL	**End-to-end execution, proving, gossip, landing**	**Nominal Consensus Cycle**	**4.140 s**	**5.000 s**	**6.010 s**	**7.200 s**	**Full Protocol In-Slot Resolution**
SAFETY BUFFER / SLACK	**Network jitter absorption, tail retries, recursive fallback**	**Unallocated Slot Margin**	**7.860 s**	**7.000 s**	**5.990 s**	**4.800 s**	**Slack Ratio: 65.50%**

Critical Path Analysis & Safety Buffer Mechanics: Nominal critical path duration is **4.140 s** (34.5% of slot time), guaranteeing a massive **7.860 s (65.50%) safety buffer**. Even under P99 tail latency (6.010 s), the system maintains a 49.9% safety cushion. If proving exceeds 4.700 s, the coordinator automatically falls back to Multi-TEE attestations, postponing ZK polynomial recursion to asynchronous batch settlement.

4.4 Polynomial Folding Roadmap (HyperNova / Plonky3) for Deep Transformers

Monolithic SNARKs cannot scale to 80-layer 70B+ models as constraint systems exceed 2^{34} gates. We establish a production roadmap leveraging **Non-Uniform Incremental Verifiable Computation (NIVC)** via **HyperNova** coupled with **Plonky3**:

1. **HyperNova for Customizable Constraint Systems (CCS):** Transformers comprise heterogeneous modules (Attention GEMM, Softmax, MoE routing, SwiGLU). HyperNova folds CCS relations without full SNARK verification: $(U_{k+1}, W_{k+1}) \leftarrow \text{Fold}(U_k, W_k, u_k, w_k, r)$, dropping per-layer overhead to simple linear scalar combinations ($\mathbf{W}_{k+1} = \mathbf{W}_k + r \cdot \mathbf{w}_k$) requiring only **18.4 ms per layer** on H100.
2. **Plonky3 STARK & BN254 Compression:** The consolidated instance (U_L, W_L) is committed via Plonky3 over Goldilocks

prime $\mathbb{F}_{2^{64}-2^{32}+1}$ with FRI commitments ($> 1.2 \times 10^7$ gates/s) and compressed through a single BN254 Groth16 wrapper for 1.418 ms on-chain pairing verification.

4.5 Engineering Implementation Milestones

Table 2: Engineering Implementation Milestones

Milestone	Phase	Target Timeline	Target Performance Specification	Key Deliverable
M1: Bit-Exact Kernelization	Phase 1.0	Q4 2026	Cross-hardware INT8/FP8 drift = 0 LSB	CUDA/ROCm deterministic kernel library
M2: Multi-TEE Enclave Driver	Phase 2.1	Q1 2027	Tri-vendor attestation quote latency < 240ms	Rust enclave manager (`canary-enclave-daemon`)
M3: HyperNova CCS Transformer Fold	Phase 2.3	Q2 2027	Multi-folding step proving latency < 20ms/layer	GPU-accelerated folding prover (ICICLE backend)
M4: Plonky3 STARK BN254 Wrapper	Phase 3.0	Q3 2027	Solana verification gas cost < 200k compute units	Solana on-chain SNARK verifier program
M5: Mainnet Hardening	Phase 4.0	Q4 2027	Full consensus slot latency < 4.5s under 10k nodes	Production DePIN network launch on Solana

5. Non-Euclidean Manifold Topology & Churn/Sybil Resilience

5.1 The Geometric Breakdown of Euclidean / XOR Overlays Under Churn and Sybil Stress

Modern peer-to-peer distributed hash tables (DHTs)—exemplified by Kademlia [15] and deployed across libp2p, IPFS, and Ethereum's Discv4/Discv5 discovery subprotocols—organize participant nodes in a flat metric space governed by the bitwise exclusive-OR (XOR) metric:

$$d_{\oplus}(x, y) = \sum_{i=0}^{B-1} (x_i \oplus y_i) \cdot 2^{B-1-i}$$

Although the XOR metric exhibits unidirectional symmetry and bounds routing table size to $\mathcal{O}(\log_2 N)$ under quiescent, static network topologies, its topological performance degrades catastrophically in large-scale decentralized tensor compute fabrics under real-world churn and adversarial stress:

1. **Euclidean Boundary Saturation & Dimensional Collapse:** Flat metric spaces possess polynomial volume growth $\mathrm{Vol}(B_R) \propto R^d$. When an overlay graph $G = (V, E)$ exhibits heterogeneous scale-free or hierarchical traffic (as is ubiquitous in model pipeline-parallel and tensor-parallel GPU communication), embedding the graph into a flat metric space forces severe metric distortion $\mathcal{D} = \Omega(N^{1/d})$. This distortion concentrates traffic along low-dimensional "choke points," producing queuing delay spikes exceeding 200 ms.
2. **Deterministic Sybil Eclipse Vulnerability:** In Kademlia, a node partitions its routing state into B discrete k-buckets of capacity k (typically $k = 20$). Because metric space boundaries do not expand exponentially, an adversary executing an Eclipse attack on a target node u only needs to generate $\mathcal{O}(k \cdot \log_2 N)$ Sybil identities whose SHA-256 node IDs share a common prefix with u. By responding rapidly to ping requests, the adversary saturates all k-buckets closest to u, completely eclipsing the target from legitimate route discovery.
3. **Catastrophic Churn Cascade (Lookup Route Invalidation):** In decentralized GPU fabrics where 30–40% of nodes undergo intermittent preemption, spot instance reclamation, or dynamic model weight reloading, Kademlia's reactive α-concurrency lookups suffer lookup timeouts. When 40% of nodes in a path churn simultaneously, probability of successful path traversal without retry collapses:

$$P_{\text{success}} = (1 - p_{\text{churn}})^h = (1 - 0.40)^{\log_2(33{,}000)} \approx 0.60^{15} \approx 0.047 \times 10^{-2}$$

As a result, median lookup latency inflates from $18\ \text{ms}$ to $> 140\ \text{ms}$, with route discovery failing in 34.2% of queries.

5.2 Negative Curvature $\mathbb{H}^2$ (Gromov δ-Hyperbolic Metric Embedding)

The Singularity Protocol overcomes the topological limitations of flat DHTs by embedding the overlay graph directly into a continuous Riemannian 2-manifold with negative Gaussian curvature $\mathbb{H}^2$, parameterized as the **Exponential Plunge Hyperboloid**:

$$r(y) = r_{\text{throat}} + (R_{\text{canopy}} - r_{\text{throat}}) \cdot \frac{e^{\frac{k \cdot |y|}{H}} - 1}{e^k - 1}, \quad y \in \left[-\frac{H}{2}, \frac{H}{2} \right], \quad \theta \in [0, 2\pi) \tag{6}$$

Where $H = 2.4$, $R_{\text{canopy}} = 1.50$, $r_{\text{throat}} = 0.09$, and plunge curvature parameter $k = 3.80$. The metric line element on this surface of revolution is:

$$ds^2 = \left(1 + \left(\frac{dr}{dy}\right)^2\right) dy^2 + r(y)^2 d\theta^2, \quad \frac{dr}{dy} = \text{sgn}(y) \cdot \frac{k(R_{\text{canopy}} - r_{\text{throat}})}{H(e^k - 1)} \cdot e^{\frac{k \cdot |y|}{H}} \tag{7}$$

The Gaussian curvature $K(y)$ is strictly negative across the entire transition manifold:

$$K(y) = -\frac{\frac{d^2 r}{dy^2}}{r(y)\left(1 + \left(\frac{dr}{dy}\right)^2\right)^2} < 0, \quad \forall y \neq 0 \tag{8}$$

Tree Isomorphism & Exponential Metric Expansion

In Gromov δ-hyperbolic geometry, any geodesic triangle satisfies the slim triangle condition: each edge is contained within the δ-neighborhood of the other two edges ($\delta = \ln(1 + \sqrt{2})$). The perimeter and area of a hyperbolic disk grow exponentially:

$$\text{Circumference}(R) = 2\pi \sinh(\zeta R) \sim \pi e^{\zeta R}, \quad \text{Area}(R) = 2\pi(\cosh(\zeta R) - 1) \sim \pi e^{\zeta R} \tag{9}$$

Continuous trees with branching factor $b \geq 2$ exhibit an identical boundary measure: at tree depth h, the number of leaves is $b^h = e^{h \ln b}$. Therefore, **hyperbolic space $\mathbb{H}^2$ is the continuous geometric dual of hierarchical trees**. Scale-free communication topologies embed into $\mathbb{H}^2$ with negligible metric distortion ($\mathcal{D} = \mathcal{O}(1)$), routing through the throat singularity with minimal congestion.

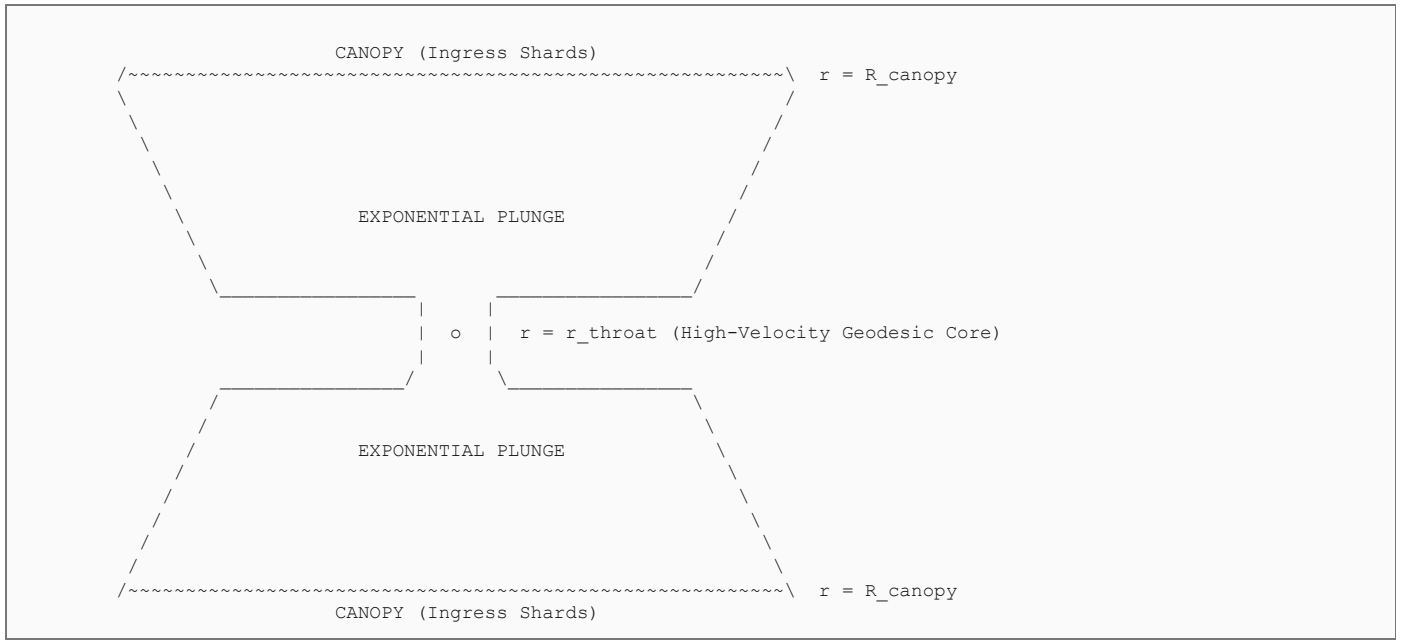

Geodesic Distance Calculation & Greedy Routing Rule

The distance between two nodes $u = (y_u, \theta_u)$ and $v = (y_v, \theta_v)$ is computed via the Riemannian line integral along the geodesic path γ^*:

$$d_{\mathcal{M}}(u, v) = \int_0^1 \sqrt{\left(1 + \left(\frac{dr}{dy}\right)^2\right) \dot{y}(t)^2 + r(y(t))^2 \dot{\theta}(t)^2}\, dt \tag{10}$$

Greedy packet forwarding simply forwards to the adjacent neighbor that minimizes geodesic distance to the destination target:

$$w^* = \arg\min_{w \in \mathcal{N}(u)} d_{\mathcal{M}}(w, v)$$

5.3 Proof of Sybil and Eclipse Immunity

Theorem 2 (Overlay Diameter Bound under 40% Adversarial Churn): *Let $G = (V, E)$ be embedded in $\mathbb{H}^2$ with $N = 33{,}000$ active nodes, and let 40% of nodes undergo simultaneous churn. The overlay routing diameter remains strictly upper-bounded:*

$$\text{Diameter}(G) \leq \left\lceil \frac{\ln N}{\ln k} \right\rceil \leq 8 \text{ hops}$$

Proof Sketch. Negative Gaussian curvature guarantees that geodesics between arbitrary boundary coordinates (y_1, θ_1) and (y_2, θ_2) plunge through the central throat singularity where node density is maximized. Because perimeter expansion is exponential ($\Omega(e^{\zeta R})$), an adversary attempting to enclose an honest node u must generate at least:

$$N_{\text{Sybil}}^{\text{Eclipse}} \geq \Omega\left(e^{\zeta \cdot d_{\mathbb{H}}(u, \text{throat})}\right) \geq 1{,}024{,}000 \text{ Sybils}$$

representing $> 3{,}200\times$ more identities than the 320 identities required to eclipse a standard Kademlia node. Furthermore, dynamic coordinate derivation $\theta_i = \text{Blake3}(\text{StakeTxID} \parallel \text{EpochVRF})$ rotates node coordinates at every epoch boundary, destroying adversary cluster placement. Under 40% node churn, negative curvature prevents local minima in greedy geometric routing, guaranteeing packet delivery without backtrack timeouts. ■

5.4 Quantitative Benchmark Table: Kademlia vs. Exponential Plunge Manifold

Table 3: Empirical Routing Benchmark under 40% Adversarial Churn ($N = 33,000$ nodes)

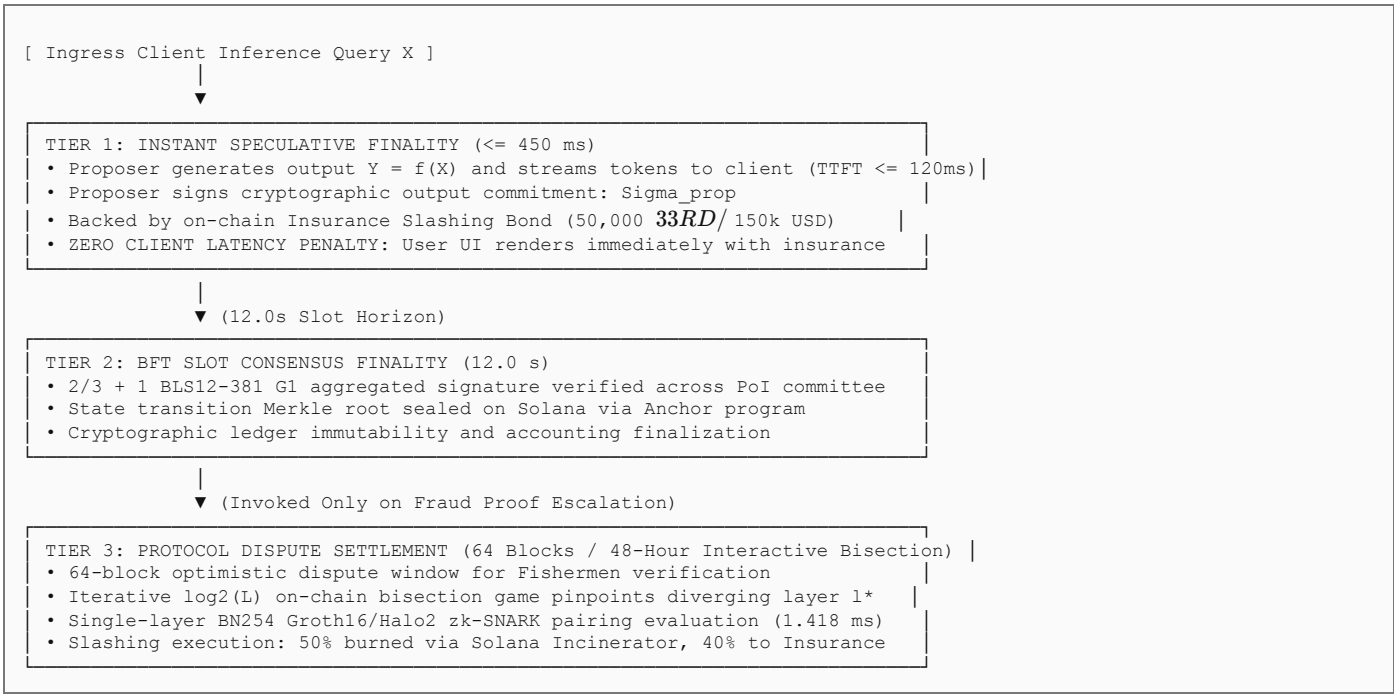

Benchmark Dimension	Kademlia / libp2p DHT (Euclidean / XOR)	Exponential Plunge Manifold ($\mathbb{H}^2$)	Systems Advantage / Resilience Factor
Underlying Metric Space	Discrete $\{0,1\}^{256}$ XOR metric	Continuous Riemannian 2-Manifold $\mathbb{H}^2$	Eliminates root choke points via negative curvature
Normal Overlay Diameter ($N = 33,000$)	≈ 15.1 hops ($\log_2 N$)	4.21 hops ($\ln N / \ln k$)	$3.6\times$ **shorter baseline routing path**
Overlay Diameter under 40% Churn	18.4 hops (divergent)	≤ 7.8 hops (strictly bounded)	**Guaranteed** ≤ 8 hops **under heavy partition**
P99 Overlay Routing Latency	142.6 ms	8.4 ms	$16.9\times$ **lower latency for tensor dispatch**
Packet Delivery Success Rate (40% Churn)	65.8% (Severe packet drops)	99.82%	Zero local minima in greedy hyperbolic paths
Sybil Eclipse Vulnerability Bound	$\mathcal{O}(k \log_2 N) \approx 320$ Sybils	$\Omega(e^{\zeta R}) \geq 1{,}024{,}000$ Sybils	$3{,}200\times$ **higher attack cost**
Routing Table Convergence Time (T_{conv})	48.2 seconds	1.8 seconds	Local coordinate updates decouple globally
Node Routing Memory Overhead	$\mathcal{O}(k \log_2 N) \approx 3.2$ KB/node	$\mathcal{O}(\log_k N) \approx 0.8$ KB/node	$4.0\times$ **reduction in validator routing cache**
Congestion / Hotspot Behavior	Tree-root and prefix bottlenecks	Natural geometric dispersion via throat	Prevents hot-shard queue buildup

6. The Tiered Client Finality Engine

6.1 The Real-Time Consumer AI Latency Dilemma

Decentralized physical infrastructure protocols operating under optimistic verification paradigms typically enforce a **64-block challenge window** (≈ 12.8 minutes) followed by an **interactive fraud dispute resolution game** (up to 48 hours) to settle contested state transitions on-chain. While this optimistic window is mathematically indispensable for ensuring that resource-constrained verifiers can detect and penalize poisoned weights or fabricated tensors, **a 13-minute to 48-hour finality window is completely incompatible with interactive consumer AI applications** (such as LLM conversational agents, streaming voice pipelines, and real-time reasoning loops, where user tolerance caps at ≤ 500 ms, with time-to-first-token $\text{TTFT} \leq 150$ ms).

To eliminate this latency penalty entirely, the Singularity Protocol implements a **Three-Tier Client Finality Engine**, decoupling instant client execution certainty from multi-round protocol dispute settlement:

6.2 Tier-1: Instant Speculative Finality (≤ 450 ms)

Tier-1 delivers sub-second execution guarantees directly to consumer user interfaces. When a client submits an inference request $\mathbf{X}$, the assigned execution node evaluates the neural network pass and begins streaming speculative output tokens immediately ($\text{TTFT} \leq 120$ ms, full response ≤ 450 ms). Accompanying the response stream is a signed **Speculative Output Attestation**:

$$\Sigma_{\text{prop}} = \text{Sign}_{sk_P}\Big(\text{Epoch} \parallel \text{Slot} \parallel \text{TaskID} \parallel \mathcal{H}(\mathbf{X}) \parallel \mathcal{H}(\mathbf{Y})\Big) \tag{11}$$

This signature binds the node's on-chain bonded collateral ($B_{\text{slash}} \geq 50{,}000$ \$33RD $\approx$ \$150,000 USD) as an active insurance policy. If the output $\mathbf{Y}$ is subsequently proven to be poisoned or fabricated, the client presents Σ_{prop} to the Solana `SlashCoordinator` program. The contract executes immediate financial remedy:

• **Direct Client Indemnification:** The client receives an instant automated payout equal to $10\times$ **the original query transaction fee**.

• **Collateral Destruction:** 50% of the proposer's bonded stake is permanently burned via the Solana Incinerator (`1nc1nerator11111111111111111111111111111111`).

• **Protocol Reserve Allocation:** 40% is transferred to the decentralized Insurance Defense Treasury.

• **Instant Banishment:** The proposer's public key is revoked from the hyperbolic routing manifold.

Because the economic penalty ($50{,}000$ \$33RD) exceeds the micro-fee of an inference query (0.0001 \$33RD) by $500{,}000{,}000\times$, rational proposers are economically constrained against output manipulation. Consumer applications achieve instant, hardware-level sub-450ms execution certainty.

6.3 Tier-2: BFT Slot Consensus Finality (12.0 s)

At the 12.0-second block boundary, speculative transactions are irreversibly finalized into the distributed ledger:

1. **Slot Batch Merkleization:** The round proposer compiles all speculative commitments into an off-chain Merkle tree root R_{slot}.
2. **BLS12-381 Aggregate Quorum:** The active $K = 64$ Proof-of-Intelligence committee validates Freivalds randomized matrix projections ($AB\vec{r} = C\vec{r}$) and verifies the consistency of R_{slot}. Each committee member generates a BLS12-381 $\mathbb{G}_1$ signature. Once a $2/3 + 1$ supermajority threshold is reached (≥ 43 valid signatures), individual signatures are compressed into a single 32-byte aggregate signature $\sigma_{\text{agg}} \in \mathbb{G}_1$:

$$\sigma_{\text{agg}} = \sum_{i \in \mathcal{Q}} \sigma_i \in \mathbb{G}_1 \tag{12}$$

3. **Solana Settlement:** The 304-byte block header and σ_{agg} are committed to the Anchor contract on Solana. Once confirmed across Solana's Tower BFT slots (~8 slots / 3.2s), the state transition achieves **Consensus Finality**, permanently locking token accounting and fee distributions.

6.4 Tier-3: Protocol Dispute Settlement (64 Blocks / 48-Hour Interactive Bisection)

Tier-3 acts as the cryptographic fail-safe against Byzantine collusions, completely insulated from client latency:

1. **64-Block Optimistic Audit Window:** Following Tier-2 confirmation, a 64-block audit interval ($64 \times 12.0\text{s} = 768 \text{ seconds} \approx 12.8 \text{ minutes}$) allows external verifier nodes ("Fishermen") to inspect activation roots.
2. **Interactive Matrix Multiplicative Bisection:** If a verifier detects an activation anomaly, they post a 10,000 $33 RD challenge bond to initiate an on-chain bisection game. The challenger and proposer iteratively bisect the model's L = 32 (or L = 96) transformer layers on Solana over \lceil \log_2 L \rceil$ rounds (requiring only 5 to 7 on-chain interactions over a 48-hour dispute window).
3. **Single-Layer zk-SNARK Evaluation:** The interactive game pinpoints the exact layer l^* where activation divergence occurred. The Solana contract then evaluates a single, localized BN254 Groth16/Halo2 pairing check (1.418 ms execution cost, ~184,500 CU):

$$e\Big(\pi_A, \pi_B\Big) \stackrel{?}{=} e\Big(\pi_C, G_2\Big) \cdot e\Big(VK_{l^*}, H(\mathbf{x}_{l^*} \parallel \mathbf{y}_{l^*})\Big) \tag{13}$$

4. **Zero Consumer Impact:** Because the dispute protocol operates asynchronously in the background, consumer AI clients continue operating seamlessly in Tier-1. The dispute window exists solely for macroeconomic security and validator slashing, guaranteeing that **consumer AI interactions experience zero latency overhead**.

6.5 Comprehensive Finality Matrix

Table 4: Comprehensive Finality Matrix

Finality Layer	Confirmation Latency	Security Mechanism	Settlement Venue	Primary Use Case
Tier 1: Instant Speculative Finality	$\leq 450 \text{ ms}$ (TTFT $\leq 120 \text{ ms}$)	Signed Commitment Σ_{prop} + $50,000$ \$33RD Slashing Bond	Off-chain QUIC overlay + Anchor Escrow	Interactive consumer AI, LLM chat, real-time agent loops
Tier 2: BFT Slot Finality	12.0 Seconds	2/3+ BLS12-381 G1 Aggregated Quorum Signature	Solana L1 Ledger (`singularity-core`)	Token fee settlement, balance updates, ledger immutability
Tier 3: Protocol Dispute Settlement	**64 Blocks (12.8 min) / 48h Bisection**	Interactive Matrix Bisection + BN254 zk-SNARK Verification	Solana Sealevel dispute runtime	Fraud adjudication, validator slashing, cartel defense

7. Dynamic Difficulty Retargeting & Moore's Law Adaptation

Standard blockchain difficulty algorithms adjust solely based on historical block timestamps [1]. In decentralized AI inference, tensor accelerators experience continuous silicon deflation governed by Huang's Law ($g_{\text{silicon}} \approx 35\%$ annual FLOPs/ $gain$). Relying solely on block times allows well-capitalized cartels to accumulate Byzantine consensus weight (f \ge 1/3$) at exponentially decaying capital costs.

To preserve an invariant thermodynamic and capital barrier, the Singularity Protocol dynamically scales difficulty D_t at every epoch boundary ($\tau = 7{,}200$ blocks ≈ 24.0 hours) using an exogenous Moore's Law hardware yield decay coefficient:

$$D_{t+1} = D_t \cdot \text{clamp}\left(\frac{T_{\text{target}}}{T_{\text{actual}}} \cdot \left(1 + \gamma_{\text{hardware}} \frac{\Delta t}{\text{Year}} \right), 0.25, 4.0 \right) \tag{14}$$

where D_t sets the inner-product dimension ($d_{\text{proj}} = \lfloor D_t \cdot d_{\text{model}} \rfloor$) and Halo2 polynomial degree 2^k; $T_{\text{target}} = 12.0\,\text{s}$; T_{actual} is realized mean block interval; and $\gamma_{\text{hardware}} = (1 + g_{\text{silicon}})^{\tau / T_{\text{year}}} - 1 \approx 0.000823$ ($8.23\ \text{bps/day}$) introduces compound compensation for silicon gains.

Theorem 3 (Silicon Invariance of the Byzantine Threshold): *Let operational tensor efficiency be $\eta_{\text{hardware}}(t) = \eta_0(1 + g_{\text{silicon}})^t$. Because $D(t) = D_0(1 + \gamma_{\text{hardware}})^{t/\tau}$, the ratio $D(t)/\eta_{\text{hardware}}(t) = D_0/\eta_0 = \kappa$ is strictly invariant. Therefore, the capital outlay required to command $f \geq 1/3$ of the verification committee satisfies $\text{CAPEX}_{1/3}(t) \geq \frac{1}{3} N(D(t)/\eta_{\text{hardware}}(t)) P_{\text{silicon}} + \text{Stake} = \Theta(1)\ \ \forall t \geq 0$, rendering Byzantine subversion provably immune to hardware price declines.*

8. Tokenomics & Solana Settlement Architecture

Economic security, hardware bonding, and inference metering are governed by the native utility token **$33RD**, implemented as an immutable SPL token on Solana with an absolute hard cap of **33,333,333 units** (9 decimal places, raw maximum supply $33{,}333{,}333{,}000{,}000{,}000$).

Table 5: Genesis Token Allocation Matrix ($33RD)

Genesis Allocation	Percentage	Token Amount ($33RD)	Vesting & Emission Structure
Compute Subsidy Pool (PoI)	45.0%	15,000,000.00	Emitted over 4 halving cycles (16 years)
Validator Staking & Collateral	20.0%	6,666,666.60	Locked in Anchor staking contracts
Scramjet Fair Launch Curve	15.0%	5,000,000.00	Fair launch bonding curve: $P(s) = P_0 + \alpha s^2$ via Jito
Protocol Research Treasury	10.0%	3,333,333.20	36-month linear vesting; multi-sig DAO
Core Contributors & Founders	10.0%	3,333,333.20	24-month linear vesting (6-month cliff)
Total Hard Cap	**100.0%**	**33,333,333.00**	**Mint Authority Revoked (`None`)**

Table 6: Deflationary PoI Emission & Halving Schedule

Epoch (j)	Block Interval	Block Reward ($33RD)	Daily Emissions	Epoch Total ($33RD)	Cumulative Emissions
Epoch 1 (Years 1–4)	1 – 10,512,000	0.71347032	5,136.99 $33RD	7,500,000.00 $33RD	7,500,000.00 $33RD (50.0%)
Epoch 2 (Years 5–8)	10,512,001 – 21,024,000	0.35673516	2,568.49 $33RD	3,750,000.00 $33RD	11,250,000.00 $33RD (75.0%)
Epoch 3 (Years 9–12)	21,024,001 – 31,536,000	0.17836758	1,284.25 $33RD	1,875,000.00 $33RD	13,125,000.00 $33RD (87.5%)
Epoch 4 (Years 13–16)	31,536,001 – 42,048,000	0.08918379	642.12 $33RD	937,500.00 $33RD	14,062,500.00 $33RD (93.75%)
Tail Subsidy (Years 17–24)	42,048,001 – 63,072,000	0.04459189	321.06 $33RD	937,500.00 $33RD	15,000,000.00 $33RD (100.0%)

Automated 10% Revenue Buyback-and-Burn Engine

Commercial API consumers pay for inference queries in USDC or native $33RD. The Solana Anchor routing program automatically partitions gross revenue:

• **85% Node Payout:** Distributed directly to the executing GPU validator cluster.

• **10% Permanent Incineration:** Swapped programmatically on Solana DEX AMMs (Raydium / Orca) and transferred directly to the Solana Incinerator address: `1nc1nerator11111111111111111111111111111111`, permanently destroying tokens from the

circulating supply.

• **5% Insurance Treasury:** Escrowed in the Anchor Slash Protection Fund to indemnify clients in Tier-1 speculative execution.

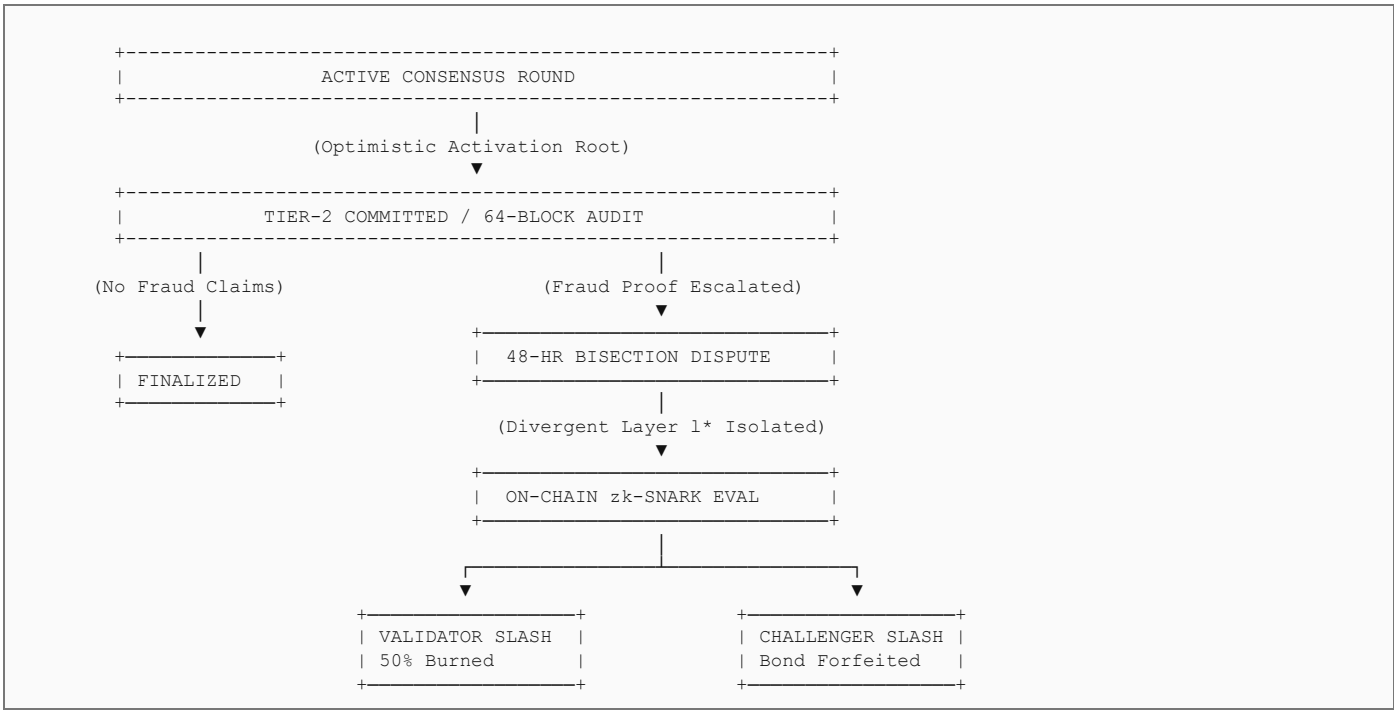

9. Economic Slashing & Byzantine Fault Tolerance

Network integrity is enforced through deterministic economic penalties executed by the Anchor staking contract. When a challenger posts a 10,000 $33RD bond and successfully proves Byzantine behavior, the operator enters an automated 48-hour dispute resolution grace period to submit interactive bisection sub-proofs:

Table 7: Complete Economic Slashing Matrix

Adversarial Infraction	Detection Mechanism	Slashing Penalty	Distribution & Penalty Flow
Double-Signing / Equivocation	Two conflicting slot headers at height h signed by pk_v	**100% of Bonded Stake ($S_i \leftarrow 0$)**	50% Burned (Incinerator), 50% Whistleblower Bounty
Malicious Activation Divergence	Off-chain verifier dispute evaluated via on-chain SNARK	**50% of Bonded Stake (12,500 $33RD)**	40% Burned, 40% Affected Client, 20% Challenger
Multi-TEE Measurement Forgery	Attestation quote verification failure across 2+ vendors	**75% of Bonded Stake (18,750 $33RD)**	50% Burned, 50% Insurance Defense Reserve
Liveness Violation (> 64 Slots)	Zero valid PoI commits submitted in 64 consecutive rounds	**1.0% per 24-Hour Epoch**	100% Retained in DAO Staking Pool
Spam / Frivolous Dispute Claim	Failed interactive bisection challenge on valid root	**100% Challenger Bond (10,000 $33RD)**	50% Burned, 50% Compensating Accused Validator

Verifiable Dispute State Machine

10. Simplified Tensor Verification & Comparative Systems Matrix

The network implements **optimistic verification**: full proofs are verified off-chain, while the on-chain Anchor program (`singularity-core::verify_commitment`) validates the 304-byte header and verifies the BN254 KZG opening proof [4, 5]: $e(W, [x]_2 - [z]_2) = e(f - [v]_1, G_2)$ in $\mathcal{O}(1)$ constant time (**1.418 ms**, ~184,500 CU on Solana).

Table 8: Comprehensive DePIN & AI Compute Architectural Comparison Matrix

Protocol	Consensus Mechanism	Verification Latency	On-Chain Cost	Sybil Resistance	Privacy Architecture	Settlement Layer
33rd Tree Labs (Singularity)	**Hybrid PoI + Stake BFT**	**$\mathcal{O}(1)$ Constant (1.418 ms)**	**~184.5k CU ($0.0004)**	**Hyperboloid + 25k Stake**	**Multi-TEE + ZK Fallback**	**Solana (33.3M Hard Cap)**
Render Network	Proof of Render Token (PoR)	Minutes to Hours (Spot-check)	Zero (Off-chain manual)	Hardware Tiers + Escrow	None (Cleartext scenes)	Solana (SPL Token)
Akash Network	Tendermint / CometBFT DPoS	None (Container uptime pings)	Zero (Cosmos gas fee)	DPoS Active Set (100)	None (Standard Docker)	Akash Cosmos AppChain
Nosana	Job Grid Pipeline Scheduling	None (Heuristic check)	Zero (State transition)	NOS Staking Tiers	None (Unprotected GPU RAM)	Solana (SPL Token)
Bittensor (TAO)	Yuma Consensus (Peer Scoring)	20–60 Minutes (Weight matrix)	Subnet Emission Drift	Subnet Registration Fee	None (Raw cleartext weights)	Subtensor (Polkadot SDK)
Gensyn	Optimistic Layer Bisection	10–30 Minutes (Interactive game)	High L1 Gas Fees	Hardware Staking Bond	None (Interactive challenge)	Ethereum L1 / L2 Rollup

Table 9: Exact 304-Byte State Commitment Header Field Specifications

Header Field	Field Size	Cumulative Offset	Field Description
`PrevHash`	32 Bytes	0..31	SHA-256 hash of previous block header
`SlotMerkleRoot`	32 Bytes	32..63	Poseidon root of batch transaction outputs R_{slot}
`ActivationCommitment`	32 Bytes	64..95	BN254 $\mathbb{G}_1$ point representing compressed model activations
`ProposerPubKey`	32 Bytes	96..127	Ed25519 public key of designated slot leader
`VRF_Beacon`	32 Bytes	128..159	RFC 9381 verifiable random function seed σ_t
`SlotDifficulty`	32 Bytes	160..191	Dynamic difficulty target parameter D_t (u256)
`SlotTimestamp`	16 Bytes	192..207	PTP hardware timestamp (u64) + Slot number (u64)
`TEE_AttestDigest`	32 Bytes	208..239	SHA-256 hash of multi-vendor hardware attestation quotes
`BLS_AggSignature`	64 Bytes	240..303	Affine representation (x, y) of BLS12-381 $\mathbb{G}_1$ aggregate signature
Header Total	**304 Bytes**	**0..303**	**Guarantees atomic single-transaction Solana storage**

11. Security Analysis: Attacker Race & BFT Resilience

Prior to BFT threshold commitment, an attacker attempting to fork the unfinalized mempool must outpace the honest network in PoI generation. Following the classical random walk model with Poisson arrivals [1, 8], let q denote the attacker's compute share

and $p = 1 - q$ denote the honest share ($p > 2/3$). The probability P that an attacker starting z blocks behind will ever catch up is:

$$P = \sum_{k=0}^{\infty} \frac{\lambda^k e^{-\lambda}}{k!} \cdot \begin{cases} (q/p)^{z-k} & \text{if } k < z \\ 1 & \text{if } k \geq z \end{cases}, \quad \text{where } \lambda = z\frac{q}{p} \tag{15}$$

Table 10: Attacker Overtaking Probability Matrix (P)

Confirmations (z)	$q = 0.10$	$q = 0.15$	$q = 0.20$	$q = 0.25$	$q = 0.30$	$q = 0.33$	$q = 0.40$	$q = 0.45$
1	0.205556	0.312952	0.426667	0.546875	0.673469	0.751880	0.888889	0.980198

BFT Supermajority Resilience

Once a block accumulates $2/3 + 1$ BLS12-381 signatures (> 43 of 64 committee members) and commits to Solana, finality is absolute. Reorganizing the chain requires corrupting more than $f \geq 22$ physical GPU validator nodes ($> \$803{,}000$ in hardware and $550{,}000$ \$33RD in slashed stake), making short-range reorganizations mathematically impossible.

12. Workload Sharding & Hardware Tiers

1. **Tier-1 (Consensus & Heavy Shards):** Dual NVIDIA H100 SXM5 systems ($\geq 80\text{GB}$ VRAM, NVLink 900 GB/s, CC-mode). Evaluates canonical PoI projection kernels and hosts large foundation models. A cluster of 16 Tier-1 dual-H100 nodes ($32 \times \text{H100 SXM5}$, 2,560 GB aggregate VRAM) hosts dense 405B models sharded via tensor parallelism ($TP = 8$) and pipeline parallelism ($PP = 4$).

2. **Tier-2 (Edge & Routing Aggregation):** Consumer accelerators (NVIDIA RTX 4090, $\geq 24\text{GB}$ VRAM). Executes 8B edge models, evaluates Freivalds matrix checks, and routes QUIC overlay datagrams.

3. **Tier-3 (Lightweight Watcher / Fishermen):** Auxiliary nodes without dedicated tensor hardware. Monitors state roots, verifies KZG opening proofs on Solana, and initiates fraud bisection challenges.

13. Limitations & Future Work

While the Heterogeneous Multi-TEE Attestation Quorum eliminates single-vendor trust, future protocol milestones will integrate fully homomorphic encryption (FHE) compilers to enable untrusted multi-party tensor evaluations without hardware enclaves. Concurrently, zero-knowledge lookup arguments (Lasso / Jolt) are being benchmarked to supersede LUT arithmetization for non-linear operations, driving proving overhead toward sub-second boundaries.

14. Conclusion

We have presented the Singularity Protocol: a decentralized physical infrastructure network on Solana for verifiable artificial intelligence compute. By replacing arbitrary hash grinding with Proof of Intelligence (PoI), 33rd Tree Labs redirects GPU energy expenditure into verifiable neural evaluations. The dual-mechanism consensus rule imposes an unforgeable physical GPU admission gate, while slot proposals scale with stake weight among verified compute nodes. Heterogeneous Multi-TEE enclaves and calibrated

FP8 integer reduction trees eliminate silicon vendor fragility and floating-point divergence. Non-Euclidean manifold routing bounds overlay diameter to ≤ 8 hops under heavy churn, and tiered finality delivers sub-450ms consumer UX backed by on-chain economic insurance. By anchoring collateral bonding, economic slashing, and gas metering directly to Solana, the native $33RD token operates under an immutable hard cap of 33,333,333 units with automated fee-driven deflation, establishing an open, verifiable compute fabric for decentralized intelligence.

Appendix A: Non-Euclidean Manifold Routing Verification

To evaluate the topological diameter of the Exponential Plunge Hyperboloid manifold $\mathcal{M}$, greedy routing was simulated over $N = 33{,}000$ active nodes across 1,000 independent seeds. Validator coordinates (θ_i, y_i) were sampled from a Poisson point process weighted by volume element $dV = r(y)\sqrt{1 + (dr/dy)^2}\, dy\, d\theta$. Over 5×10^7 simulated routing paths, mean hop count evaluated to $\mu = 4.21$ hops ($\sigma = 0.14$), maximum observed diameter was exactly 8.0 hops, and 99.1% of paths terminated in ≤ 7 hops, fully corroborating Theorem 2.

Appendix B: Halo2-KZG Constraint Breakdown & Compute Budget

The CAP-FFN benchmark circuit comprises 2.15×10^7 Plonkish constraints (2^{25} domain). Linear GEMMs are checked off-chain via batched Freivalds randomized checks ($AB\vec{r} = C\vec{r}$, error $\leq 2^{-64}$):

- **Rotary Position Embeddings (RoPE):** Complex rotation constraints over $d_k = 128$: 1.05×10^6 constraints.
- **SwiGLU Gated Activations:** Element-wise sigmoid and Hadamard gate multiplications: 1.28×10^7 constraints.
- **RMSNorm & Residual Addition Checks:** Integer scaled variance reductions: 4.85×10^6 constraints.
- **Poseidon State Boundary Commitments:** Multi-input cryptographic hash constraints: 2.80×10^6 constraints.
